

# The SMART pulsar survey: Past, present, & future

---

Bradley Meyers  
(on behalf of the SMART team)

MWA Project Meeting

25-28 July 2023

# **How it all began**

**Motivation and the inception of a MWA pulsar survey.**

# An idea is born...

By 2017 we had moved to a stage where **high time resolution processing** was becoming **more tractable** with the Voltage Capture System (VCS)

- *Offline software coherent beamformer*
  - + MWA now included in common pulsar processing packages
- *Tools and utilities to make managing processing easier* (VCSTools)
- *Local group knowledge and understanding*
  - R. Bhat, S. Ord, S. Tremblay, F. Kirsten, G. Slep, S. McSweeney, B. Meyers, M. Xue, N. Swainston...

**MWA Phase II** introduced “compact configuration” making the concept of tessellating the entire southern sky feasible - still very daunting!

# An MWA pulsar survey

With the **wide field of view** from the tile design, “**fat**” **tied-array beams** from MWA Phase II Compact tile layouts, and a **multi-pixel beamformer** on the way, it all seemed possible!

And so, the **Southern-sky MWA Rapid Two-metre pulsar survey** was conceived

- Only need *<100 observations* total (still a large ask given VCS data rates)
- *Better sensitivity* than previous Southern pulsar surveys at similar frequencies
- If all VCS observations can be stored, constitutes a *voltage record of the sky*
- Provides a *reference for SKA-Low* predictions and verification

# An MWA pulsar survey

With the **wide field of view** from the tile design, “**fat**” **tied-array beams** from MWA Phase II Compact tile layouts, and a **multi-pixel beamformer** on the way, it all seemed possible!

**SMART**

And so, the **Southern-sky MWA Rapid Two-metre pulsar survey** was conceived

- Only need *<100 observations* total (still a large ask given VCS data rates)
- *Better sensitivity* than previous Southern pulsar surveys at similar frequencies
- If all VCS observations can be stored, constitutes a *voltage record of the sky*
- Provides a *reference for SKA-Low* predictions and verification

# SMRT... I mean, SMART!

Southern-sky **M**WA **R**apid **T**wo-meter pulsar survey

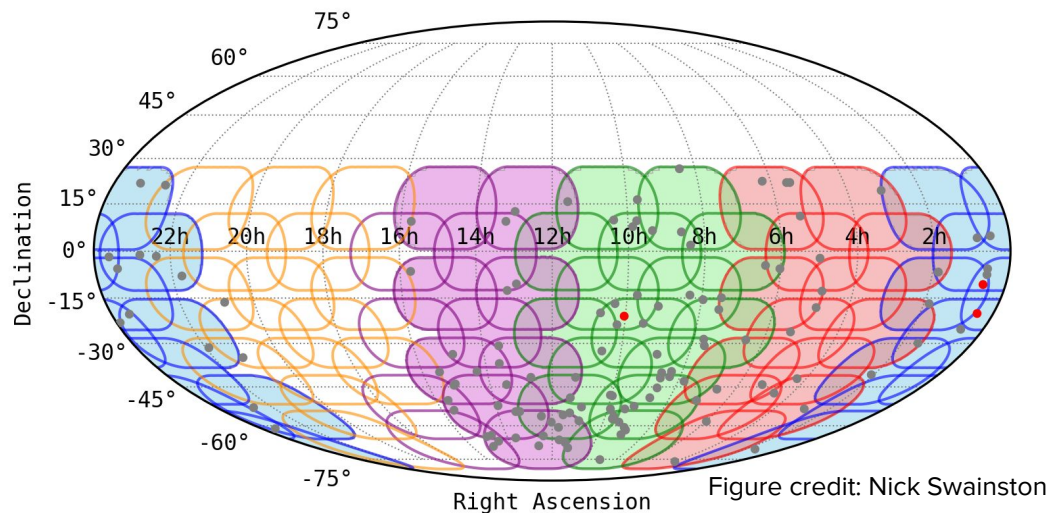

# **Current status**

**What we are doing right now.**

# How much data have we collected?

As of previous  
Project Meeting

- Collected 75% of observations needed to cover the visible sky
  - Dec range: +30 deg to SCP
  - RA range: <16hr and >21hr
  - Remaining observations will cover the Galactic Plane and Centre
    - Very interesting region, but also very difficult for low-frequencies!

- 51 VCS observations = 2.15 PB of data
  - Observed between September 2018 and May 2021

# How much data have we collected?

As of now

100%

- Collected ~~75%~~ of observations needed to cover the visible sky
  - A **voltage record of the Southern sky at 154 MHz**
- **3.6 PB** of voltage data
  - +10 TB of calibration observations (before & after each VCS obs.)
- **51 Legacy + 19 MWAX** observations
  - Legacy: observed between September 2018 and May 2021
  - MWAX: observed between January and July 2023

# How much data have we processed?

- We have successfully conducted a *proof-of-concept “first-pass” survey*
  - Only analysed the **first 10 minutes** of each observation
  - **No RFI mitigation** (beyond forming tied-array beams)
  - Used a very **coarse dedispersion plan** (2500 trials)
  - Did only a **basic periodicity search** across each time series’ power spectrum
- Processed 80% of the Legacy observations
  - Corresponds to only 8% of total data volume
  - Only a small fraction of the produced candidates have been inspected! (<10% of the 8%...)
  - Still **found a handful of new pulsars**...

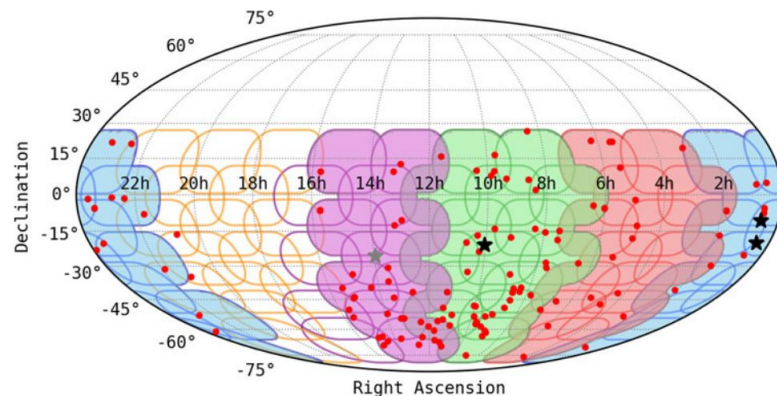

Fig. 1 in Bhat et al. 2023b

# Pulsars we have discovered

- Discovered:
  - **J0036-1033**; typical, but has a steep spectral index and low-luminosity
  - **J1002-2044**; typical, slightly steep spectral index, possibly another low-luminosity object
  - **J0452-3418**; newest addition, interesting emission phenomenology
    - See *Garvit Grover's talk for GMRT+MWA follow-up!*
- Re-discoveries:
  - **J0026-1955**; a GBNCC candidate, initially detected in a grating lobe, sub-pulse drifting
    - See *Parul Janagal's poster for GMRT follow-up!*
  - **J1357-2530**; actually detection of mislabeled PSR J1358-2533 with vastly different P and DM!
    - GMRT imaging was required to nail down position and hence update the name

# Other pulsars we have detected with SMART

We have also **detected many known pulsars** in SMART observations

- Pulsars: 170
- Millisecond pulsars: 15\*
- Binary pulsars: 15\*

Many of these are the **first detections below 300 MHz!**

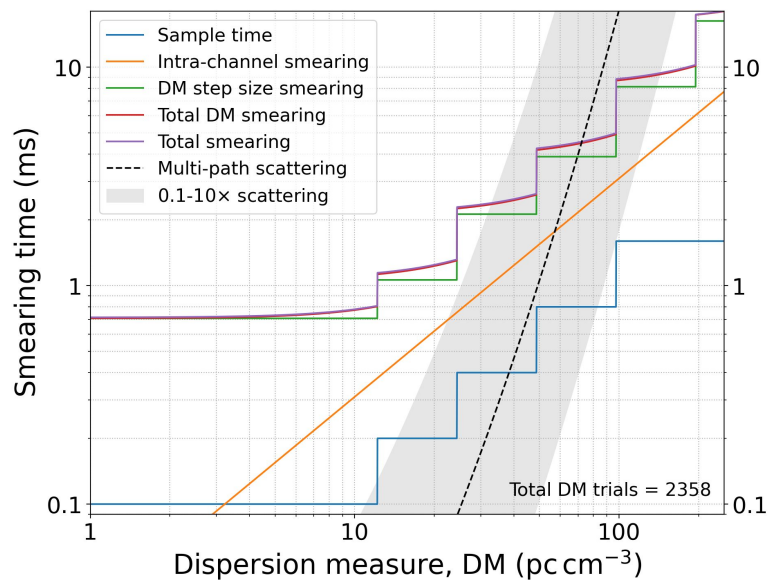

\*Not mutually exclusive.

Credit: Chris Lee

# **Planning the next stage of SMART processing**

# Optimising dedispersion plans

- Must make informed decisions based on instrumental limits
  - **Reduce artificial data degradation** by increasing DM precision
  - **Cost/benefit compromise** in terms of data generation/degradation

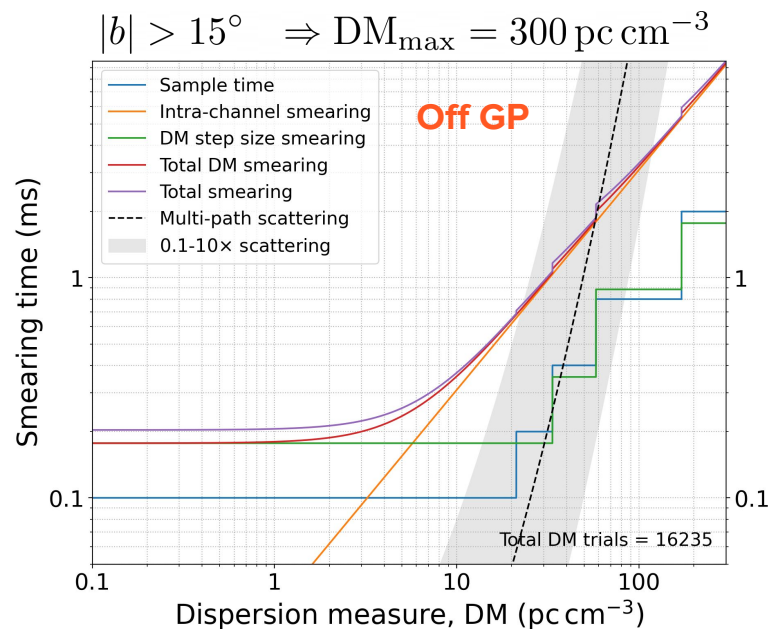

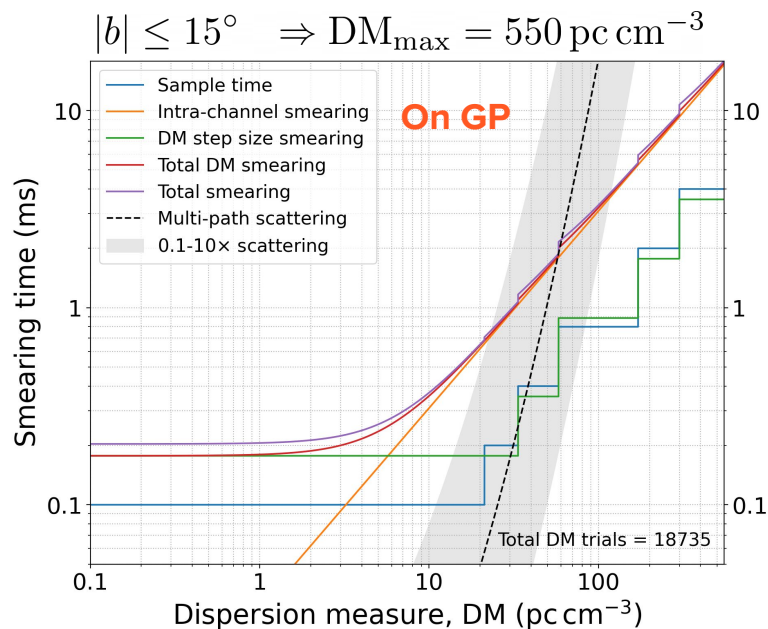

7-8x trials  
➔

# Optimising dedispersion plans

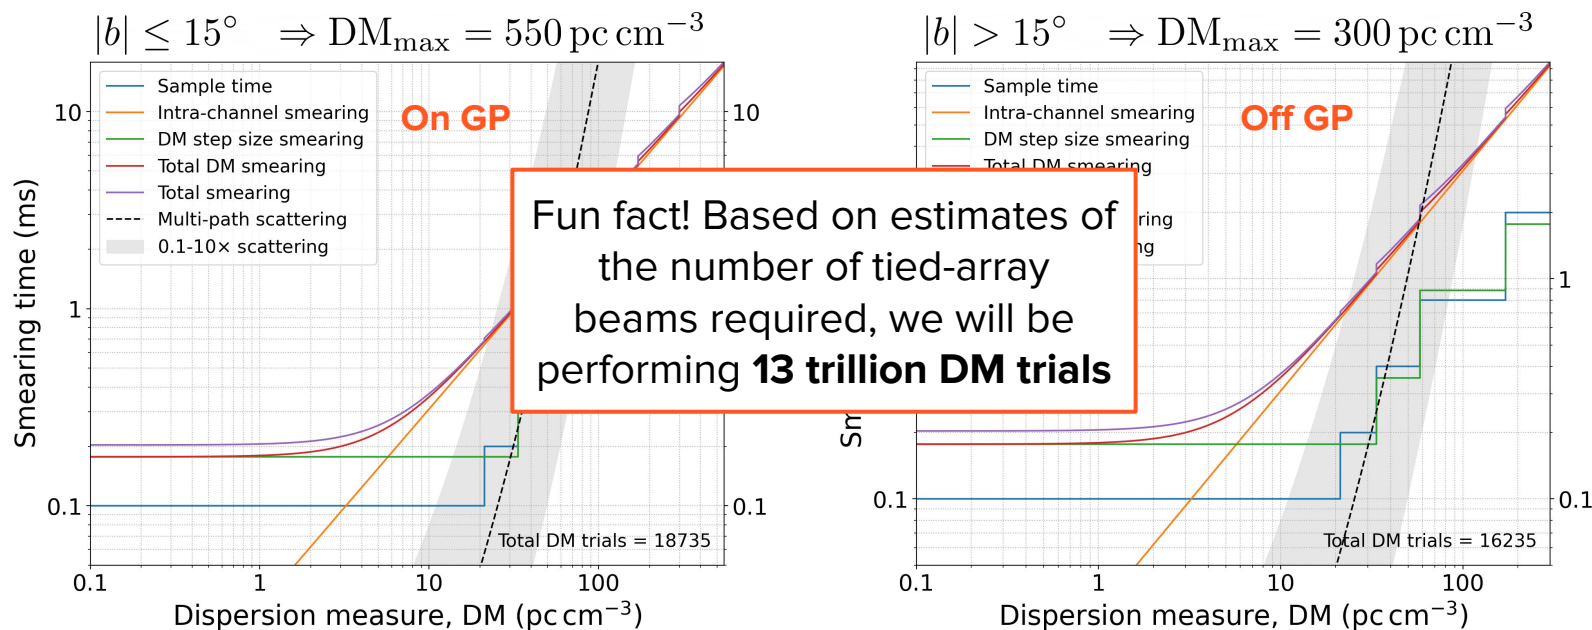

- Use two **different plans based on Galactic latitude**
  - DM rapidly increased towards the Galactic plane

# Optimising dedispersion plans

- Use two **different plans based on Galactic latitude**
  - DM rapidly increased towards the Galactic plane

# Updating our sensitivity estimates

- The dedispersion plan directly impacts theoretically achievable sensitivity
  - Also depends on pulsar period, pulse duty cycle, dwell time, and the assumed gain and system temperature

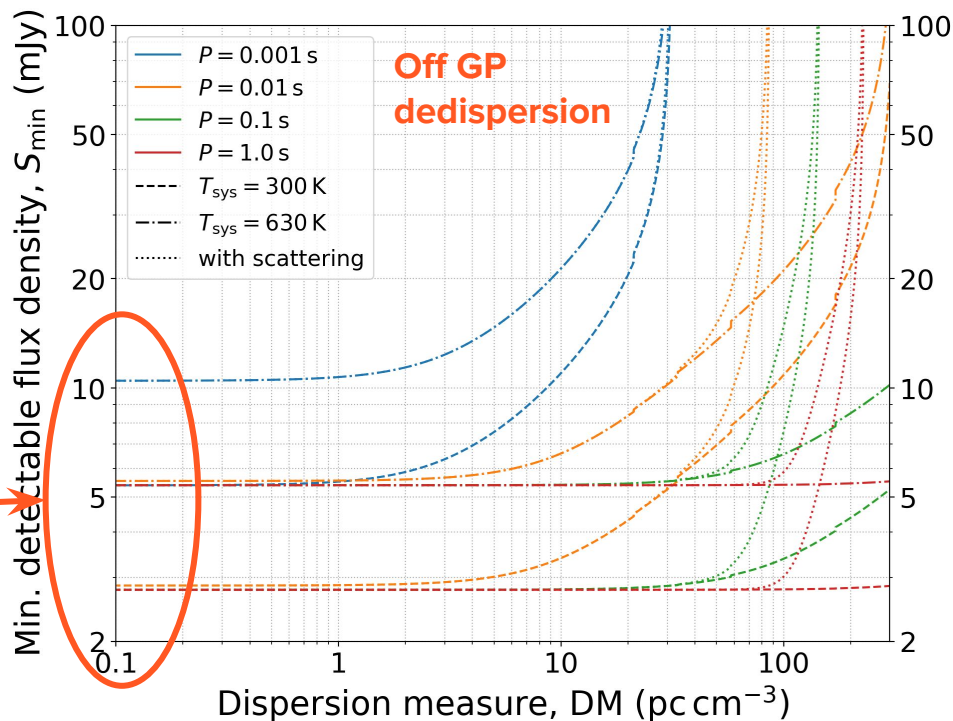

# Updating our sensitivity estimates

- The dedispersion plan directly impacts theoretically achievable sensitivity
  - Also depends on pulsar period, pulse duty cycle, dwell time, and the assumed gain and system temperature

Even at a DM of  $0.1 \text{ pc cm}^{-3}$ , our minimum effective time resolution is about  $250 \mu\text{s}$ , thus our minimum detectable flux density is worse than the “ideal” (for periods  $< 15 \text{ ms}$ ).

**Need *semi-coherent* dedispersion!**

# Bringing our database and web-app online

- Database to manage processing stages and outputs
  - Developed through ADACS (special thanks to James Tocknell)
- REST API framework linked to a web application
  - Programmatic interactions possible during Nextflow tasks (and beyond)
  - Website with documentation, survey status and candidate ranking portal
- Currently live, but still ironing out some issues
- Eventual location for SMART data product releases and hosting

<https://apps.datacentral.org.au/smart/>

# How should we *actually* search for pulsars?

- For our entire *first-pass processing*, we used about **300 kSU**\*
- For a *naive second-pass*, need about **250 kSU per observation**
  - That's  $70 \times 250 \text{ kSU} = 17500 \text{ kSU}$ !
  - A very-well graded ASTAC proposal may achieve 500-600 kSU
  - So, SMART would take... **23 years to complete**
- Need to make difficult **decisions about the scope of “second-pass”**
  - Is the proposed dedispersion plan absurd? What about RFI mitigation?
  - Can we afford any acceleration searches? Can we afford single-pulse searches?
  - Do we only process a portion of the sky? Which part? (High-*l*/*b*l is easier, but fewer pulsars...)

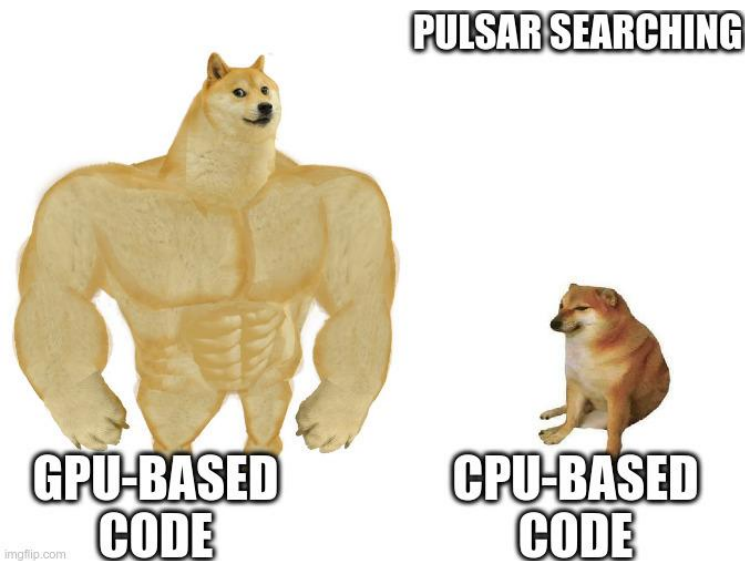

\*On OzSTAR, **1 kSU** is about **1000 CPU-hours** (or 125 GPU-hours)

**Looking to the  
future**

# Accelerating our search software

The *searching methods* are now our **biggest computational bottleneck**

- Just like our beamforming code, moving to **GPU-accelerated techniques** will be **critical in the long-run** to efficiently search such a large data volume

+ Actually it's also about Intelligent algorithmic design, efficient resource use, etc., etc.

# Reprocessing of SMART data

SMART data are voltages, retains *maximum flexibility* for various processing tasks

- Relies on being able to **archive the SMART data** in perpetuity
  - Phase 1 ARDC; 2018-2019 campaigns; allocation of 1081 TB (~40% of sky).
  - Phase 2 ARDC; 2020-2021 campaigns; allocation of 977 TB (~40% of the sky)
  - ????????????????; 2023 campaign; Galactic Plane coverage (final ~20% of the sky)

<https://asvo.mwatelescope.org/collections>

- Historically, **pulsar surveys have been processed many times over**
  - Motivated by new technologies, algorithmic developments, and/or phenomena
  - FRBs, RRATs, new MSPs and binaries...
- Next **generation telescope survey data cannot be kept** for any extended time
  - Will force creative solutions that will also aid in reprocessing SMART data!

**SMART team:** R. Bhat, B. Meyers, N. Swainston, S. McSweeney, M. Xue,, M. Sokolowski, S. Dai, S. Kudale, W. van Straten, R. Shannon, S. Tremblay, ...

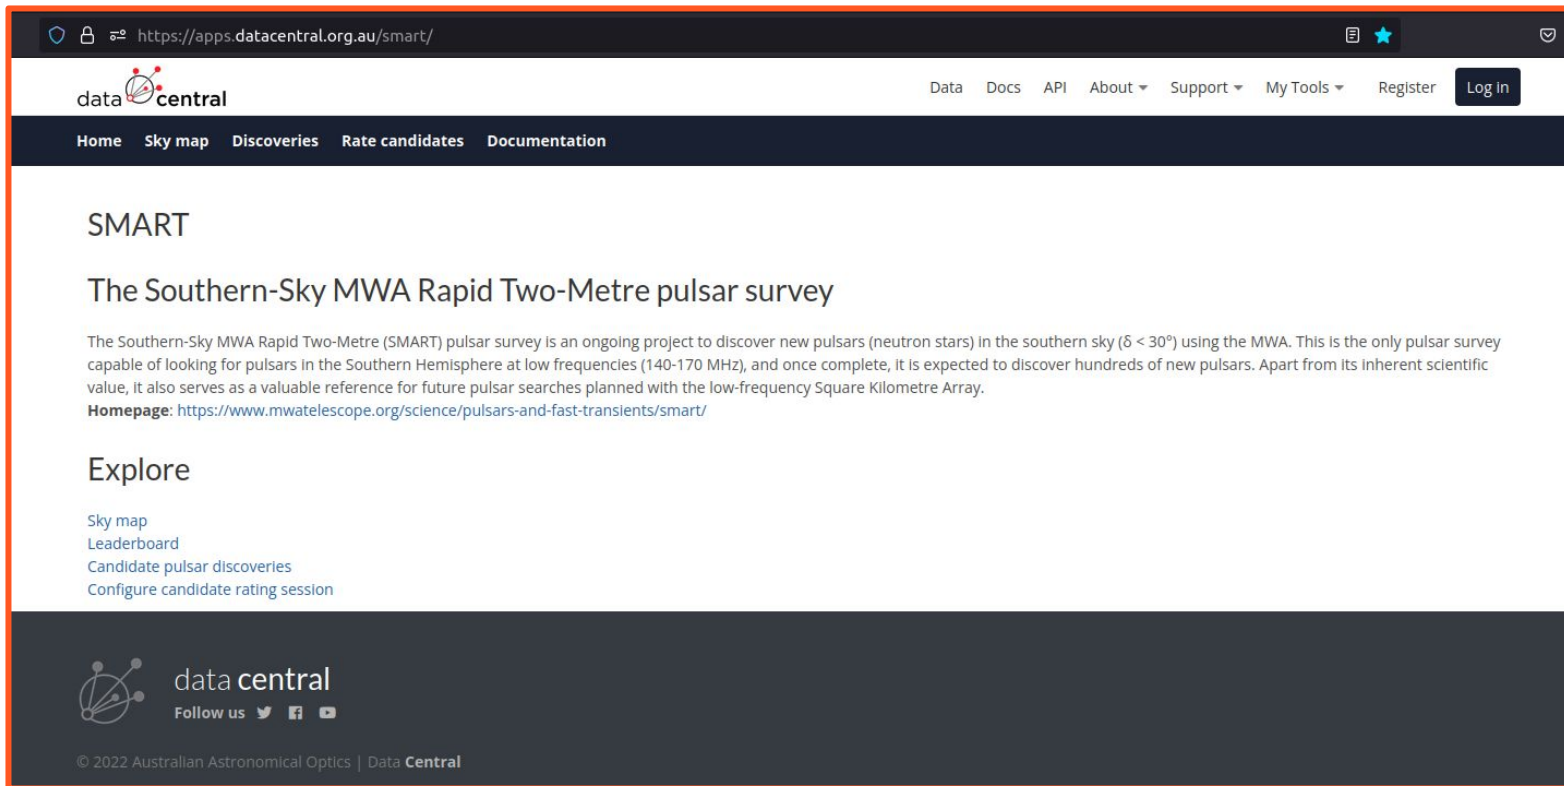

# Summary

- **Completed data collection**
  - 3.6 PB of VCS observations
  - Voltage record of the visible sky
- **Critical decisions about next processing steps**
  - The reality is we *can't* naively scale
  - Innovation & development required!
- **Handful of pulsars already!**
  - Promising for total survey yield
  - On track for >100 pulsars

**Additional slides**

# DataCentral database and web-app support

The screenshot shows a web browser window with the URL <https://apps.datacentral.org.au/smart/>. The page features the DataCentral logo and navigation links: Data, Docs, API, About, Support, My Tools, Register, and Log in. A secondary navigation bar includes Home, Sky map, Discoveries, Rate candidates, and Documentation. The main content area is titled "SMART" and "The Southern-Sky MWA Rapid Two-Metre pulsar survey". It contains a paragraph describing the project and a link to the homepage. Below this is an "Explore" section with links for Sky map, Leaderboard, Candidate pulsar discoveries, and Configure candidate rating session. The footer includes the DataCentral logo, social media icons, and the text "© 2022 Australian Astronomical Optics | Data Central".

## SMART

### The Southern-Sky MWA Rapid Two-Metre pulsar survey

The Southern-Sky MWA Rapid Two-Metre (SMART) pulsar survey is an ongoing project to discover new pulsars (neutron stars) in the southern sky ( $\delta < 30^\circ$ ) using the MWA. This is the only pulsar survey capable of looking for pulsars in the Southern Hemisphere at low frequencies (140-170 MHz), and once complete, it is expected to discover hundreds of new pulsars. Apart from its inherent scientific value, it also serves as a valuable reference for future pulsar searches planned with the low-frequency Square Kilometre Array.

# Practicality of search methods

Simulations testing FFT vs. FFA searching for SMART-like data suggests

- FFT searching should be limited to  $P < 10$  seconds
  - Red noise dominates, can mitigate but information fundamentally lost
- FFA searching most effective at  $P > 1$  second
  - Red noise removal in time domain, but still removing potential information
  - Efficiency grows for large  $P$  due to re-use of data in-memory

Proposed strategy

- FFT for: **1 ms < P < 2 s**
- FFA for: **1 s < P < 120 s**

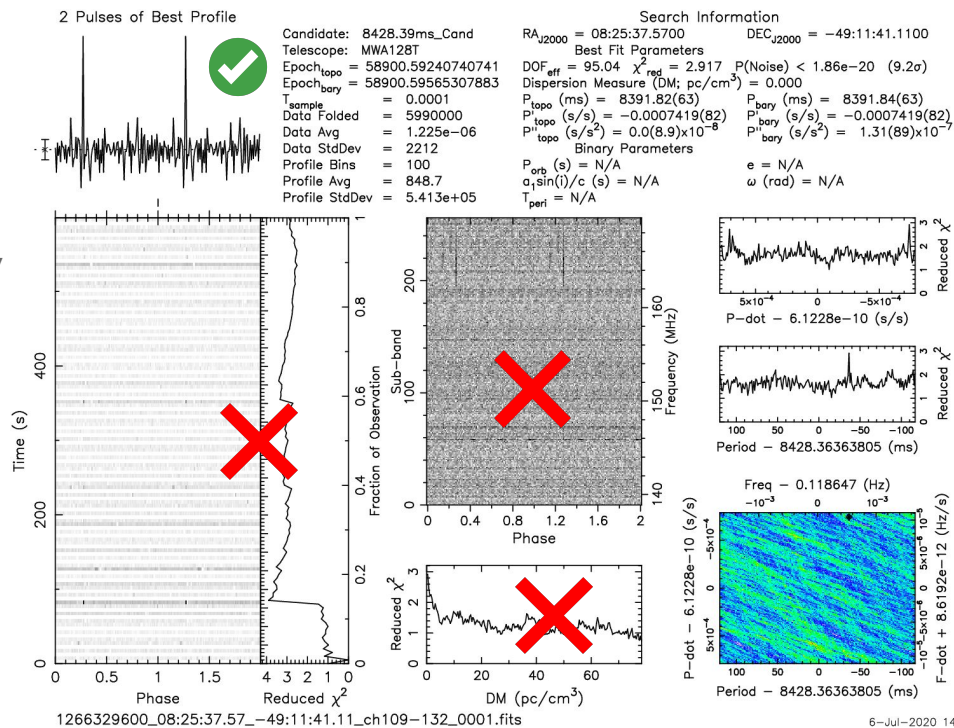

# Current state of searching software

- Almost all CPU-based, or GPU-based is developed for higher frequencies
  - A big factor for MWA is the dispersion sweep is enormous which requires equivalently enormous GPU resources to process optimally
  - **AstroAccelerate** (developed for SKA) notionally works on MWA-like data, but performance is drastically reduced due to memory limitations on all but the biggest of GPUs
  - **Peasoup** (Swinburne group) also developed for higher-frequency surveys, probably cannot handle MWA-like data without significant changes (which likely decreases efficiency)
  - **GPU-PRESTO**(?) has been on the table for years, but there is no supported/well-maintained version and no plan towards it in the near-future

# Include RFI mitigation

- Clear examples in shallow pass where RFI causes grief

- While the observatory site is exquisitely RFI quiet, we still see impulsive and periodic varieties
- RFI can mimic single pulses *and* periodic pulsar signals - they are by far the majority of candidates
- Exploring options of how to deal with these in an effective and computationally feasible way
  - RFI “excision” can happen after candidate creation, too

# RFI in pulsar data - an example

**Impulsive interference**  
(band-limited, 7 MHz wide)

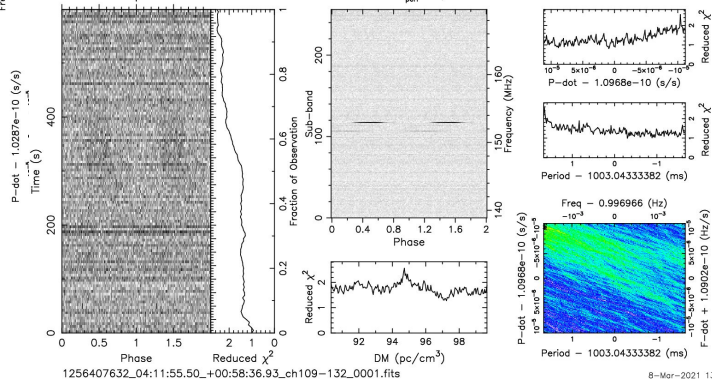

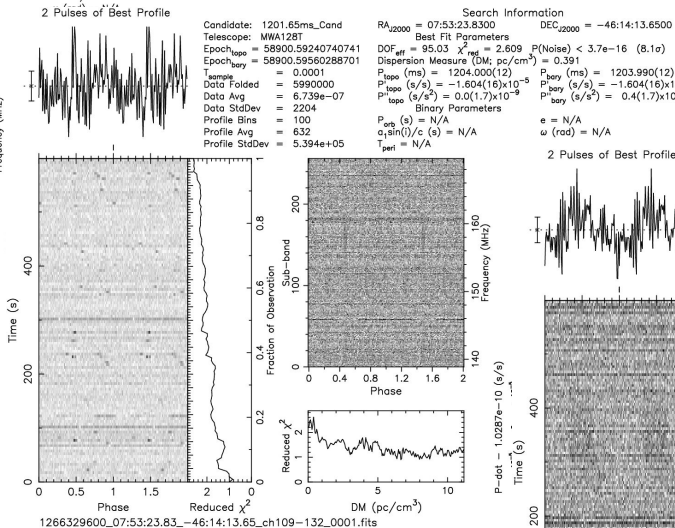

**Narrow band, periodic interference** (maybe not pure tone, but periodic enough to cause trouble)

Common periodic signals at zero DM leak into other DM trials because they are much brighter than typical pulsars.

**We need to identify and mask these signals (“birdies”) *before searching!***

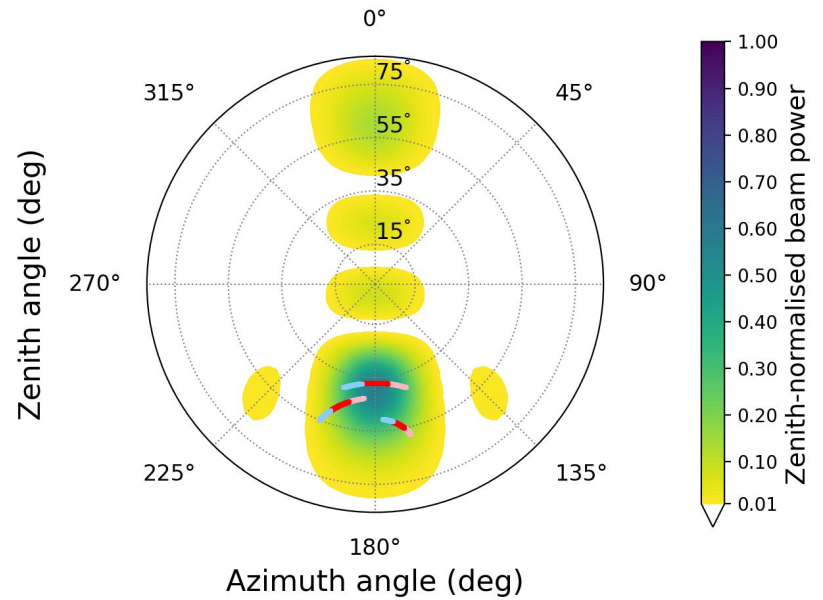

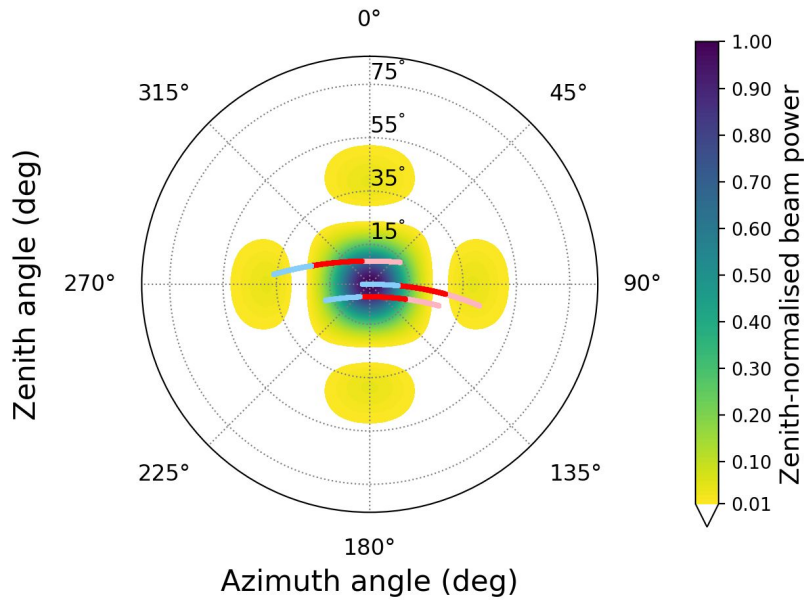

# Other RFI examples - the horrifying truth

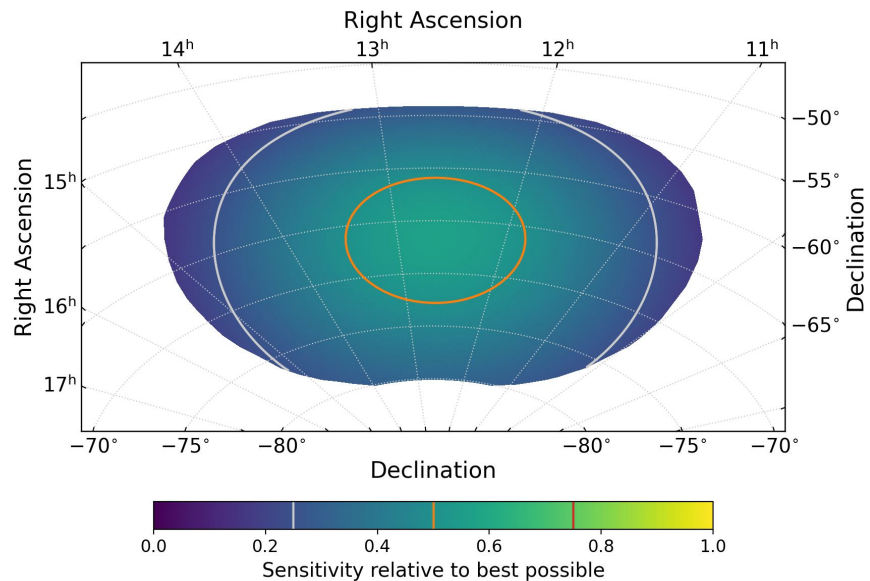

# Consider realities of our observing strategy

- How does a static primary beam combined with a sky-tracking tied-array beam impact sensitivity?
  - SMART is unique among pulsar surveys - inform considerations for SKA-Low!
- 1. Computationally inefficient to beamform all sky-positions for full 80 mins
  - Why bother forming tied-array beams when source is in a primary beam null?
- 2. Tracking position for full duration may *decrease* sensitivity
  - Consequence of 1. is that we essentially just add noise to the data when searching
  - But... longer tracks also improve chances of detecting bright single pulses and long-period pulsars
- 3. Sensitivity will be position dependent
  - Primary beam sky positions (Alt/Az) *in addition to* target sky position (RA/Dec) affects sensitivity

## Observing near vs. far-from zenith: beam pattern & source traces

**Observing near vs. far-from zenith: relative sensitivity**
